A SPATIAL-TEMPORAL ASYMPTOTIC PRESERVING SCHEME FOR RADIATION MAGNETOHYDRODYNAMICS

SHI JIN, MIN TANG, AND XIAOJIANG ZHANG

ABSTRACT. The radiation magnetohydrodynamics (RMHD) system couples the ideal magnetohydrodynamics equations with a gray radiation transfer equation. The main challenge is that the radiation travels at the speed of light while the magnetohydrodynamics changes with fluid. The time scales of these two processes can vary dramatically. In order to use mesh sizes and time steps that are independent of the speed of light, asymptotic preserving (AP) schemes in both space and time are desired. In this paper, we develop an AP scheme in both space and time for the RMHD system. Two different scalings are considered, one results in an equilibrium diffusion limit system, while the other results in a non-equilibrium system. The main idea is to decompose the radiative intensity into three parts, each part is treated differently. The performances of the semi-implicit method are presented, for both optically thin and thick regions, as well as for the radiative shock problem. Comparisons with the semi-analytic solution are given to verify the accuracy and asymptotic properties of the method.

1. Introduction

Radiation magnetohydrodynamics (RMHD) is concerned about the dynamical behaviors of magnetized fluids that have nonnegligible exchange of energy and momentum with radiation, which is important in high temperature flow systems, solar and space physics and astrophysics. The radiation transfer equation (RTE) for the radiative intensity $I$ and the fluid temperature $T$ in the mixed frame is governed by

$$\frac{\partial I}{\partial t} + C n \cdot \nabla I = C \sigma_a \left( \frac{a_r T^4}{4\pi} - I \right) + C \sigma_s (J - I) + 3n \cdot \nu \sigma_a \left( \frac{a_r T^4}{4\pi} - J \right) + \nu \cdot (\sigma_a + \sigma_s)(I + 3J) - 2\sigma_s v \cdot H - (\sigma_a - \sigma_s) \frac{v \cdot v}{C} J - (\sigma_a - \sigma_s) \frac{v \cdot (v \cdot K)}{C},$$

where $\sigma_a$ and $\sigma_s$ represent absorption and scattering opacities respectively, $n \in V$ is the angular variable, $a_r$ is the radiation constant and $C$ is the speed of light [7]. The ideal MHD equations with radiation energy and momentum source terms are

$$\begin{align*}
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho v) &= 0, \\
\frac{\partial (\rho v)}{\partial t} + \nabla \cdot (\rho vv - BB + P^*) &= -S_{rp}, \\
\frac{\partial E}{\partial t} + \nabla \cdot [(E + P^*)v - B(B \cdot v)] &= -CS_{rc}, \\
\frac{\partial B}{\partial t} + \nabla \times (v \times B) &= 0,
\end{align*}$$

where

$$S_{rc} = \sigma_a(a_r T^4 - E_r) + (\sigma_a - \sigma_s) \frac{v}{C^2} \cdot [F_r - (v E_r + v \cdot P_r)],$$

$$S_{rp} = -\frac{\sigma_s + \sigma_a}{C} [F_r - (v E_r + v \cdot P_r)] + \frac{v}{C} \sigma_a(a_r T^4 - E_r),$$

Date: January 12, 2021.
with the energy density
\[ E_r = 4\pi J = \frac{4\pi}{|V|} \int_V I \, d\mathbf{n} = 4\pi \langle I \rangle, \]
the radiation flux
\[ F_r = 4\pi C \mathbf{H} = \frac{4\pi C}{|V|} \int_V \mathbf{n} I \, d\mathbf{n} = 4\pi \langle n I \rangle, \]
and the radiation pressure
\[ P_r = 4\pi K = \frac{4\pi}{|V|} \int_V n^2 I \, d\mathbf{n} = 4\pi \langle n^2 I \rangle. \]
In particular, the operators \( \langle \cdot \rangle \), \( \langle n \cdot \rangle \) and \( \langle n^2 \cdot \rangle \) are respectively \( \frac{1}{|V|} \int_V \cdot \, d\mathbf{n} \), \( \frac{1}{|V|} \int_V \mathbf{n} \cdot \, d\mathbf{n} \) and \( \frac{1}{|V|} \int_V n^2 \cdot \, d\mathbf{n} \) in context. Moreover, \( \rho \) is fluid density, \( \mathbf{v} \) is fluid velocity, \( \mathbf{B} \) is magnetic flux density, \( p \) is static pressure, \( \mathbf{P}^* \) is full pressure of fluid, \( \mathbf{P}^* \equiv (p + B^2/2)M \) (with \( M \) the unit tensor), and the total fluid energy density is
\[ E = E_g + \frac{1}{2}\rho v^2 + \frac{B^2}{2}, \]
where \( E_g \) is the internal energy density, \( v^2 = \mathbf{v} \cdot \mathbf{v} \) and \( B^2 = \mathbf{B} \cdot \mathbf{B} \). The radiation MHD system is closed by the perfect gas equation of state:
\[ E_g = p/(\gamma - 1), \quad T = p/(\gamma \text{ideal} \rho), \]
where \( \gamma \) is adiabatic index for an ideal gas, and \( \gamma \text{ideal} \) is the ideal gas constant.

Numerical approximations to RTE have been extensively studied in [12,14,15,21,24,30] and for ideal MHD see for example [2,18,29]. The RMHD coupled system has been investigated lately [1,6,7,13,27,28,31]. Since the transport term in the RTE and the advection term in the MHD equations are at different time scales, the RMHD system can be stiff, as can been seen more clearly after nondimensionalization [19]. To solve the RMHD system, classical numerical discretizations require the space and time steps resolve the speed of light, which leads to very expensive computational cost. Asymptotic-Preserving (AP) schemes provide a generic framework for such multiscale problems [8,9]. AP schemes were first studied for steady neutron transport problems in diffusive regimes [16,17] and then [5,10] for boundary value problems, and unsteady transport problems [11,14]. In the discrete setting, from the microscopic scale to the macroscopic, AP schemes preserve the asymptotic limit. When the scaling parameter \( \varepsilon \) in the multiscale system can not be resolved numerically, AP schemes should automatically become a good solver for the macroscopic models.

AP schemes for RMHD have been proposed in the literature but since most of them are based on operator splitting, they are only AP in space. In [1], Simon et al. have developed a second-order scheme in both space and time for the Euler equations coupled with a gray radiation \( S_2 \) model. The scheme in [1] uses MUSCL-Hancock method to solve the Euler equations and the lumped linear-discontinuous Galerkin method for the radiation \( S_2 \) model. For the time discretization, the TR/BDF2 time integration method is employed. Jiang et al. devised an Implicit/Explicit (IMEX) scheme for the splitting system that treats the transport term in the RTE and convective term in the fluid equations explicitly, and the source term implicitly [7]. Recently, another method by Sun etc. [31] uses the gas-kinetic scheme (GKS) to deal with Euler equations and the unified gas-kinetic scheme (UGKS) for the RTE. However, all the aforementioned methods either require a time step that satisfies a hyperbolic constraint with CFL number proportional to the light speed [1,7], or use nonlinear iterations involving (1.1) in order to get rid of the time step constraint [31]. Both approaches are expensive. It is desired to design a scheme that can use a time step that is independent of the light speed and employs nonlinear iterations that involve only macroscopic quantities, i.e. the \( \rho, \mathbf{v}, E, \mathbf{B} \) or the moments of radiative intensity.

In this paper, we aim at developing a scheme for RMHD that is AP in both space and time. Two different parameter regimes are considered. One is for \( \sigma_a \) small and \( \sigma_s \) large, which results in the nonequilibrium diffusion limit system. The other is for \( \sigma_a \) large, which gives the equilibrium diffusion limit.
system. The proposed scheme preserves both limits. The main idea is to decompose the intensity into three parts, two parts correspond to the zeroth and first order moments, while the third part is the residual. The two macroscopic moments are treated implicitly while the residual is explicit. Thanks to the properties of residual term, one can update the macroscopic quantities first. For the space discretization, we use Roe’s method in the Athena code to solve the convective part in the ideal MHD equations and the UGKS for the RTE. AP property of both semi-discretized and fully discretized are proved.

This paper is organized as follows. Section 2 gives the asymptotic limit of the coupled system, and the equilibrium and non-equilibrium diffusion limit systems under different scalings are obtained. The semi-discretization and one dimensional fully discretized scheme for RMHD are illustrated in Sections 3 and 4 respectively. Their capability of capturing both diffusion limits are proved. In Section 5, performances of the proposed scheme preserves both limits. The main idea is to decompose the intensity into three parts, two parts correspond to the zeroth and first order moments, while the third part is the residual. The two macroscopic moments are treated implicitly while the residual is explicit. Thanks to the properties of residual term, one can update the macroscopic quantities first. For the space discretization, we use Roe’s method in the Athena code to solve the convective part in the ideal MHD equations and the UGKS for the RTE. AP property of both semi-discretized and fully discretized are proved.

2. The diffusion limit of RMHD

As presented in [19], the dimensionless form for the coupled system can give a better insight on the relative importance of different terms. Consider the following nondimensionalization:

\[
\begin{align*}
    x &= \hat{x} \ell_\infty, & t &= \hat{t} \ell_\infty / a_\infty, & \rho &= \hat{\rho} \rho_\infty, & \mathbf{v} &= \hat{\mathbf{v}} a_\infty, & p &= \hat{p} \rho_\infty a_\infty^2, & T &= \hat{T} T_\infty, & I &= a_r T_\infty^4 \hat{I}, \\
    E_r &= a_r T_\infty^4 \hat{E}_r, & \mathbf{F}_r &= C_a T_\infty^4 \hat{\mathbf{F}}_r, & P_r &= a_r T_\infty^4 \hat{P}_r, & \sigma_a &= \lambda_a \hat{\sigma}_a, & \sigma_s &= \lambda_s \hat{\sigma}_s,
\end{align*}
\]

where variables with a hat denote nondimensional quantity and variables with \( \infty \)-subscript are the characteristic value with unit. More precisely, \( \ell_\infty, a_\infty, \rho_\infty \) and \( T_\infty \) are respectively the reference length, sound speed, density and temperature. Moreover, \( \lambda_a \) and \( \lambda_s \) are respectively the characteristic value of absorbing and scattering coefficients. Then the full dimensionless radiation MHD system becomes

\[
\begin{align*}
    \frac{\partial I}{\partial t} + \mathbf{C} \cdot \nabla I &= \mathcal{L}_a \mathcal{C}_a \left( \frac{T_\infty^4}{4\pi} - I \right) + \mathcal{L}_s \mathcal{C} (J - I) + 3 \mathcal{L}_a \mathbf{n} \cdot \mathbf{v} \sigma_a \left( \frac{T_\infty^4}{4\pi} - J \right) + \mathbf{n} \cdot \mathbf{v} (\mathcal{L}_a \sigma_a + \mathcal{L}_s \sigma_s) (I + 3J) \\
    \frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) &= 0, \\
    \frac{\partial (\rho \mathbf{v})}{\partial t} + \nabla \cdot (\rho \mathbf{v} \mathbf{v} - \mathbf{B} \mathbf{B} + P^*) &= -\mathcal{P}_0 \mathbf{S}_{\mathbf{r} \mathbf{p}}, \\
    \frac{\partial E}{\partial t} + \nabla \cdot [(E + P^*) \mathbf{v} - \mathbf{B} (\mathbf{B} \cdot \mathbf{v})] &= -\mathcal{C} \mathcal{P}_0 \mathbf{S}_{\mathbf{r} \mathbf{e}}, \\
    \frac{\partial \mathbf{B}}{\partial t} + \nabla \times (\mathbf{v} \times \mathbf{B}) &= 0,
\end{align*}
\]

where \( \mathcal{C} = \frac{C}{a_\infty}, \mathcal{P}_0 = \frac{a_r T_\infty^4}{\rho_\infty \sigma_\infty}, \mathcal{L}_a = \ell_\infty \lambda_a, \mathcal{L}_s = \ell_\infty \lambda_s, \mathcal{S}_{\mathbf{r} \mathbf{e}} = 4\pi \langle S \rangle \) and \( \mathbf{S}_{\mathbf{r} \mathbf{p}} = 4\pi \langle nS \rangle \). In (2.1), \( \mathcal{P}_0 \) is a nondimensional constant, which measures the influence of radiation on the flow dynamics. In [4], the authors considered the equilibrium diffusion regime and non-equilibrium diffusion regime for a simplified coupled system. In the subsequent part, we consider the equilibrium diffusion limit and non-equilibrium diffusion limit of the RMHD system by using the same scaling assumptions as in [4].

2.1. The non-equilibrium diffusion limit. In the simulation of radiation-hydrodynamics in [1], the speed of light \( C = 29.98 \text{ cm ns}^{-1} \), in nonrelativistic flows the sound speed is \( 0.001386 \text{ cm ns}^{-1} \), the radiation constant \( a_r = 0.001372 \text{ Jk cm}^{-3} \text{ KeV}^{-4} \), the typical computational domain is 0.04 cm, and the units of the
length, time, temperature and energy are respectively $cm$, $ns$, $KeV$ and $Jk$. Therefore $1/C = O(\varepsilon)$, $P_0 = O(1)$. In non-equilibrium regime, we assume $\mathcal{L}_a = \varepsilon$, $\mathcal{L}_s = 1/\varepsilon$, and the radiation intensity $I$ tends to a state which can be characterized by a temperature which is different from the material temperature $T$. In summary, we consider the following scaling

$$\mathcal{L}_a = \varepsilon, \quad \mathcal{L}_s = 1/\varepsilon, \quad P_0 = O(1), \quad C = c/\varepsilon.$$ 

The RMHD system (2.1) becomes (after dropping the hat):

$$\begin{aligned}
&\frac{\partial I}{\partial t} + -\frac{c}{\varepsilon} \eta \cdot \nabla I = \alpha_\sigma \left( \frac{T^4}{4\pi} - I \right) + \frac{\alpha_\sigma}{\varepsilon^2} (J - I) + 3\varepsilon n \cdot \n u \sigma_a \left( \frac{T^4}{4\pi} - J \right) + n \cdot \n \left( \varepsilon \sigma_a + \frac{\sigma_s}{\varepsilon} \right) (I + 3J) \\
&- 2\varepsilon \sigma \eta \cdot H - (\varepsilon^2 \sigma_a - \sigma_s) \frac{\n \cdot \n K}{\varepsilon} = 0, \\
\end{aligned}$$

(2.2a)

$$\begin{aligned}
&\frac{\partial P}{\partial t} + \nabla \cdot (\rho \n) = 0, \\
&\frac{\partial (\rho \n)}{\partial t} + \nabla \cdot (\rho \n \n \n - BB + P^*) = -P_0 S_{rp}, \\
&\frac{\partial E}{\partial t} + \nabla \cdot [(E + P^*) \n - B(B \cdot \n)] = -\frac{c}{\varepsilon} P_0 S_{re}, \\
&\frac{\partial B}{\partial t} + \nabla \times (\n \times B) = 0, \\
\end{aligned}$$

(2.2b-c)

where

$$S_{re} = \varepsilon \sigma_a \left( T^4 - \frac{4\pi}{|V|} \int_V I \eta d\eta \right) + \left( \varepsilon^3 \sigma_a - \varepsilon \sigma_s \right) \frac{4\pi}{c|V|} \left[ \frac{c}{\varepsilon} \int_V n I \eta d\eta - \left( \varepsilon \int_V I \eta d\eta + \int_V n^2 I \eta d\eta \right) \right],$$

$$S_{rp} = -\frac{4\pi (\sigma_a + \varepsilon^2 \sigma_s)}{c|V|} \left[ \frac{c}{\varepsilon} \int_V n I \eta d\eta - \left( \varepsilon \int_V I \eta d\eta + \int_V n^2 I \eta d\eta \right) \right] + \frac{c}{\varepsilon} \varepsilon \sigma \left( \frac{T^4}{4\pi} - \frac{4\pi}{|V|} \int_V I \eta d\eta \right).$$

When $\varepsilon \to 0$, we show that the solution to (2.2) can be approximated by the solution to a nonlinear diffusion equation coupled with a MHD system. We assume that the radiation intensity $I$ and temperature $T$ have the following Chapman-Enskog expansion such that

$$I = I^{(0)} + \varepsilon I^{(1)} + \varepsilon^2 I^{(2)} + \cdots,$$

$$T = T^{(0)} + \varepsilon T^{(1)} + \varepsilon^2 T^{(2)} + \cdots.$$ 

(2.3)

By substituting ansatz (2.3) into equation (2.2a) and collecting the terms of the same order in $\varepsilon$, we have

$$\mathcal{O} \left( \frac{1}{\varepsilon^2} \right) : I^{(0)} = J^{(0)},$$

(2.4a)

$$\mathcal{O} \left( \frac{1}{\varepsilon} \right) : \eta n \cdot \nabla I^{(0)} = \alpha_\sigma \left( J^{(1)} - I^{(1)} \right) + n \cdot \n u \sigma_a \left( I^{(0)} + 3J^{(0)} \right).$$

(2.4b)

Multiplying both sides of (2.2a) by $n$, taking its integral with respect to $n$ and combining the obtained equation with (2.2c), one can get the following momentum conservation equation:

$$\eta t \left( \frac{\rho n}{P_0} + \frac{4\pi c}{c} \langle n I \rangle \right) + \nabla \cdot \left( \frac{\rho v - BB + P^*}{P_0} + 4\pi \langle n^2 I \rangle \right) = 0. $$

(2.5)

By using (2.4a) and $\langle n^2 \rangle = \frac{1}{4}$, when $\varepsilon \to 0$, (2.5) gives

$$\eta t \left( \rho^{(0)} v^{(0)} \right) + \nabla \cdot \left( \rho^{(0)} v^{(0)} v^{(0)} - B^{(0)} B^{(0)} \right) + (P^*)^{(0)} = -\frac{4\pi P_0}{3} \nabla J^{(0)}.$$ 

(2.6)

By taking the integral with respect to $n$ on both sides of (2.2a), and combining it with (2.2d), one can obtain the energy conservation equation

$$\eta t \left( \frac{E}{P_0} + 4\pi \langle I \rangle \right) + \nabla \cdot \left( \frac{(E + P^*) v - B(B \cdot v)}{P_0} + \frac{4\pi c \langle n I \rangle}{\varepsilon} \right) = 0.$$ 

(2.7)
By using (2.4a), when \( \varepsilon \to 0 \), (2.7) gives
\[
\partial_t \left( \frac{E^{(0)}}{P_0} + 4\pi \langle I^{(0)} \rangle \right) + \nabla \cdot \left[ \frac{(E^{(0)} + (P^{*})^{(0)})v^{(0)} - B^{(0)}(B^{(0)} \cdot v^{(0)})}{P_0} + 4\pi c \langle nI^{(1)} \rangle \right] = 0.
\]
Noting (2.4b), we find
\[
\partial_t \left( E^{(0)} + 4\pi P_0 J^{(0)} \right) + \nabla \cdot \left[ (E^{(0)} + (P^{*})^{(0)})v^{(0)} - B^{(0)}(B^{(0)} \cdot v^{(0)}) + \frac{16\pi P_0}{3} v^{(0)} J^{(0)} - \frac{4\pi c P_0}{3\sigma_s} \nabla J^{(0)} \right] = 0.
\]
(2.2b), (2.6), (2.8) and (2.2e) give four equations for \( \rho, \rho v, E, J, B \), to obtain one more equation for \( J \). Taking \( \langle \cdot \rangle \) on both sides of equation (2.2a), yields:
\[
\partial_t \langle I \rangle + \frac{c}{\varepsilon} \nabla \cdot \langle nI \rangle = \frac{c}{4\pi \varepsilon} S_{re}.
\]
By using the expansion in (2.3) and (2.4a), the leading order terms are
\[
4\pi \partial_t \langle I^{(0)} \rangle + 4\pi c \nabla \cdot \langle nI^{(1)} \rangle = c\sigma_a \left( (T^{(0)})^4 - 4\pi \langle I^{(0)} \rangle \right) - 4\pi \sigma_s \left[ \frac{v^{(0)}}{c} \right] \left[ c \langle nI^{(1)} \rangle - v^{(0)} \left( \langle I^{(0)} \rangle + \langle n^2 I^{(0)} \rangle \right) \right],
\]
then from (2.4b), one gets
\[
4\pi \partial_t J^{(0)} + \nabla \cdot \left( \frac{16\pi}{3} v^{(0)} J^{(0)} - \frac{4\pi c}{3\sigma_s} \nabla J^{(0)} \right) = c\sigma_a \left( (T^{(0)})^4 - 4\pi J^{(0)} \right) + \frac{4\pi}{3} v^{(0)} \nabla J^{(0)}.
\]
Therefore, when \( \varepsilon \to 0 \) in (2.2), the solution can be approximated by the solution of the following nonequilibrium system:
\[
\begin{align*}
\partial_t \rho + \nabla \cdot (\rho v) &= 0, \\
\partial_t (\rho v) + \nabla \cdot (\rho vv - BB + P^*) &= -\frac{4\pi P_0}{3} \nabla J, \\
\partial_t (E + 4\pi P_0 J) + \nabla \cdot \left[ (E + P^*)v - B(B \cdot v) + \frac{16\pi P_0}{3} v J \right] &= \nabla \cdot \left( \frac{4\pi c P_0}{3\sigma_s} \nabla J \right), \\
4\pi \partial_t J + \nabla \cdot \left( \frac{16\pi}{3} v J - \frac{4\pi c}{3\sigma_s} \nabla J \right) &= c\sigma_a \left( T^4 - 4\pi J \right) + \frac{4\pi}{3} v \nabla J, \\
\partial_t B + \nabla \times (v \times B) &= 0.
\end{align*}
\]
Here, the non-equilibrium system indicates that \( J \) is away from \( \frac{T^4}{4\pi} \), while we will see in section 2.2 that the equilibrium diffusion limit indicates that \( J \approx \frac{T^4}{4\pi} \).

2.2. The equilibrium diffusion limit. The setting of \( P_0 \) and \( C \) in this regime are the same with the non-equilibrium regime. Moreover, we assume \( \mathcal{L}_s = 1/\varepsilon, \mathcal{L}_a = \varepsilon \), and the radiation intensity \( I \) adapt to the material temperature. In summary, we consider the following scaling
\[
\mathcal{L}_a = 1/\varepsilon, \quad \mathcal{L}_s = \varepsilon, \quad P_0 = \mathcal{O}(1), \quad C = c/\varepsilon.
\]
This is called the equilibrium diffusion regime, which will give the classical equilibrium diffusion limit [19, 23, 25]. The RMHD system (2.1) becomes (after dropping the hat):

\[
\begin{align*}
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v}) &= 0, \\
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho \mathbf{v} - \mathbf{B} \mathbf{B} + P^*) &= -P_0 S_{re}, \\
\frac{\partial E}{\partial t} + \nabla \cdot [(E + P^*) \mathbf{v} - \mathbf{B} (\mathbf{B} \cdot \mathbf{v})] &= -\frac{c}{\varepsilon} P_0 S_{re}, \\
\frac{\partial \mathbf{B}}{\partial t} + \nabla \times (\mathbf{v} \times \mathbf{B}) &= 0,
\end{align*}
\] (2.11a-2.11e)

where

\[
S_{re} = \frac{\rho_a}{\varepsilon} \left( T^4 - \frac{4\pi}{|V|} \int_V I d\mathbf{n} \right) + (\varepsilon \sigma_a - \varepsilon^3 \sigma_a) \frac{4\pi \mathbf{v}}{c^2 |V|} \cdot \left[ \frac{c}{\varepsilon} \int_V n I d\mathbf{n} - \left( \mathbf{v} \int_V I d\mathbf{n} + v \int_V n^2 I d\mathbf{n} \right) \right],
\]

\[
S_{rp} = -\frac{4\pi (\varepsilon^2 \sigma_a + \sigma_a)}{c |V|} \left[ \frac{c}{\varepsilon} \int_V n I d\mathbf{n} - \left( \mathbf{v} \int_V I d\mathbf{n} + v \int_V n^2 I d\mathbf{n} \right) \right] + \frac{v}{c} \sigma_a \left( T^4 - \frac{4\pi}{|V|} \int_V I d\mathbf{n} \right).
\]

Using the same expansion as in (2.3), one has

\[
T^4 = (T^{(0)} + \varepsilon T^{(1)} + \varepsilon^2 T^{(2)} + \cdots)^4
= (T^{(0)})^4 + \frac{4\varepsilon}{7} (T^{(0)})^3 T^{(1)} + \cdots.
\] (2.12)

Then substituting (2.12) into (2.11a) and collecting the terms of the same order of \( \varepsilon \), one gets

\[
\mathcal{O} \left( \frac{1}{\varepsilon^2} \right) : I^{(0)} = \frac{(T^{(0)})^4}{4\pi},
\]

\[
\mathcal{O} \left( \frac{1}{\varepsilon} \right) : c \mathbf{n} \cdot \nabla I^{(0)} = c \sigma_a \left( \frac{4(T^{(0)})^3 T^{(1)}}{4\pi} - I^{(1)} \right) + \mathbf{n} \cdot \mathbf{v} \sigma_a \left( I^{(0)} + \frac{3(T^{(0)})^4}{4\pi} \right),
\] (2.13a-2.13b)

by similar calculations in section 2.1, one can get the following equilibrium diffusion limit:

\[
\begin{align*}
\partial_t \rho + \nabla \cdot (\rho \mathbf{v}) &= 0, \\
\partial_t (\rho \mathbf{v}) + \nabla \cdot (\rho \mathbf{v} - \mathbf{B} \mathbf{B} + P^*) &= -\frac{P_0}{3} \nabla T^4, \\
\partial_t (E + P_0 T^4) + \nabla \cdot \left[ (E + P^*) \mathbf{v} - \mathbf{B} (\mathbf{B} \cdot \mathbf{v}) + \frac{4P_0}{3} v T^4 \right] &= \nabla \cdot \left( \frac{c P_0}{3 \sigma_a} \nabla T^4 \right), \\
\partial_t \mathbf{B} + \nabla \times (\mathbf{v} \times \mathbf{B}) &= 0.
\end{align*}
\] (2.14a-2.14d)

As we can see, when \( J = \frac{T^4}{4\pi} \) in (2.10), the non-equilibrium diffusion system (2.10) is the same as the equilibrium diffusion system (2.14), which indicates \( J \) is close to \( \frac{T^4}{4\pi} \) in the equilibrium system (2.11).

### 3. Time discretization for the RMHD

In this section, based on a decomposition for radiation intensity \( I \), we will present a semi-discretization for the RMHD and show its AP property for any dimensions in space and angular variables.
3.1. A decomposition. To preserve the asymptotic limit of (2.1) while keeping the computational complexity under control, the intensity \( I \) will be decomposed into three parts, and each of them is treated in a different way. More precisely, we decompose \( I(t, x, n) \) as follows:

\[
I(t, x, n) = \langle I \rangle + 3n \langle nI \rangle + \varepsilon Q(t, x, n),
\]

(3.1a)

\[
:= J(t, x) + \varepsilon nR(t, x) + \varepsilon Q(t, x, n),
\]

(3.1b)

with \( 3\langle nI \rangle = \varepsilon R \). Then taking \( \langle n \cdot \rangle \) on both sides of (3.1a) and using the condition \( \langle n^2 \rangle = \frac{1}{3} \) yields

\[
\langle nI \rangle = \langle nI \rangle + \varepsilon \langle nQ \rangle,
\]

which gives

\[
\langle nQ \rangle = 0.
\]

(3.2)

Moreover, taking \( \langle \cdot \rangle \) on (3.1b), yields

\[
\langle I \rangle = \langle J + \varepsilon nR + \varepsilon Q \rangle = \langle J + \varepsilon Q \rangle = \langle I \rangle + \varepsilon \langle Q \rangle,
\]

which implies

\[
\langle Q \rangle = 0.
\]

(3.3)

Substituting the decomposition (3.1) into system (2.2) leads to

\[
\begin{aligned}
\partial_t (J + \varepsilon (nR + Q)) + \frac{c}{\varepsilon} n \nabla \cdot (J + \varepsilon (nR + Q)) &= ca_a \left( \frac{T^4}{4\pi} - J \right) - \left( \varepsilon \sigma_a + \frac{\varepsilon \sigma_s}{\varepsilon} \right) (nR + Q) \\
- \frac{2}{3} \sigma_s vR + \nabla \cdot (\varepsilon \sigma_a + \frac{\sigma_s}{\varepsilon}) (4J + \varepsilon (nR + Q)) + 3\varepsilon \sigma_a n\nu \left( \frac{T^4}{4\pi} - J \right) &= \left( \varepsilon^2 \sigma_a - \frac{\sigma_s}{\varepsilon} \right) v \cdot v \left( \frac{4}{3} J + \varepsilon K_Q \right),
\end{aligned}
\]

(3.4a)

\[
\begin{aligned}
\frac{\partial \rho}{\partial t} + \nabla \cdot (\rho v) &= 0, \\
\frac{\partial (\rho v)}{\partial t} + \nabla \cdot (\rho vv - BB + P^*) &= -P_0 \vec{S}_{re}, \\
\frac{\partial E}{\partial t} + \nabla \cdot [(E + P^*)v - B(B \cdot v)] &= -\frac{c}{\varepsilon} P_0 \vec{S}_{re}, \ \\
\frac{\partial B}{\partial t} + \nabla \times (v \times B) &= 0,
\end{aligned}
\]

(3.4b–3.4e)

where \( K_Q = \langle n^2 Q \rangle \) and

\[
\begin{aligned}
\vec{S}_{re} &= \varepsilon \sigma_a (T^4 - 4\pi J) + 4\pi (\varepsilon^3 \sigma_a - \varepsilon \sigma_s) \frac{v}{c^2} \left[ \frac{c}{3} R - v \left( \frac{4}{3} J + \varepsilon K_Q \right) \right], \\
\vec{S}_{rp} &= -\frac{4\pi (\sigma_s + \varepsilon^2 \sigma_a)}{c} \left[ \frac{c}{3} R - v \left( \frac{4}{3} J + \varepsilon K_Q \right) \right] - \frac{\varepsilon^2 v}{c} \sigma_a (T^4 - 4\pi J).
\end{aligned}
\]

(3.4a) has three unknown functions, \( J, R \) and \( Q \). Thanks to the properties of \( Q \) in (3.2), (3.3), the zeroth and first moment equations of (3.4a) have no time derivatives with respect to \( Q \). Therefore, instead of solving the RMHD system (3.4) directly, we take the zeroth and first moments of (3.4a), and then couple them together with (3.4b)--(3.4e) to solve variables \( \rho, J, R, v, T, B \). More precisely, we have

\[
\begin{aligned}
\partial_t J + \frac{c}{3} \nabla \cdot R &= \frac{c}{4\pi \varepsilon} \vec{S}_{re}, \\
\varepsilon \frac{\partial R}{\partial t} + \frac{c}{3\varepsilon} \nabla \cdot J + c \nabla \cdot K_Q &= \frac{c}{4\pi \varepsilon} \vec{S}_{rp},
\end{aligned}
\]

(3.5)

coupled with (3.4b)--(3.4e) and by treating \( K_Q \) explicitly, one can update the macroscopic quantities first. Then \( Q \) can be updated implicitly by the first equation in system (3.4a), and the new \( I \) can be given by (3.1). The details are illustrated in the next two subsections.
3.2. The time discretization for the non-equilibrium regime. Let
\[ t^s = s\Delta t, \quad s = 0, 1, 2, \ldots, \]
and
\[ I^s \approx I(x, t^s, n), \quad \rho^s \approx \rho(x, t^s, n), \quad v^s \approx v(x, t^s, n), \]
\[ T^s \approx T(x, t^s, n), \quad B^s \approx B(x, t^s, n). \]

We use the following semi-discrete scheme in time for (3.4), which reads:
\[
\begin{cases}
\frac{J^{s+1} - J^s}{\Delta t} + \varepsilon n \frac{R^{s+1} - R^s}{\Delta t} + \varepsilon Q^{s+1} - Q^s + \frac{c}{\varepsilon} n \nabla \cdot J^{s+1} + c n \nabla \cdot (n R^{s+1} + Q^s) \\
= c \sigma_s \left( \frac{(T^{s+1})^4}{4\pi} - J^{s+1} \right) - \left( \varepsilon \varepsilon \sigma_s + \frac{c \sigma_s}{\varepsilon} \right) (n R^{s+1} + Q^{s+1}) - \frac{2}{3} \sigma_s v^{s+1} R^{s+1} \\
+ 3 \varepsilon \sigma_s n v^{s+1} \left( \frac{(T^{s+1})^4}{4\pi} - J^{s+1} \right) + n v^{s+1} \left( \varepsilon \sigma_s + \frac{\sigma_s}{\varepsilon} \right) (4 J^{s+1} + \varepsilon (n R^{s+1} + Q^s)) \\
- (\varepsilon^2 \sigma_s - \sigma_s) \frac{v^{s+1} \cdot v^{s+1}}{c} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q^s \right),
\end{cases}
\]
\[ \text{(3.6a)} \]
\[
\begin{cases}
\frac{\rho^{s+1} - \rho^s}{\Delta t} + \nabla \cdot (\rho^s v^s) = 0, \\
\frac{\rho v^{s+1} - (\rho v)^s}{\Delta t} + \nabla \cdot (\rho^s v^s v^s - B^s B^s + (P^s)^s) = -P_0(S_{rp})^{s+1}, \\
\frac{\rho T^{s+1} - (\rho T)^s}{\Delta t} + \rho v^{s+1} (v^s v^s) - \rho^s (v^s)^2 + (B^{s+1})^2 - (B^s)^2 \\
+ \nabla \cdot [(E^s + (P^s)^s) v^s - B^s (B^s \cdot v^s)] = -\frac{c}{\varepsilon} P_0(S_{re})^{s+1},
\end{cases}
\]
\[ \text{(3.6b, 3.6c, 3.6d)} \]
\[
\begin{cases}
\frac{B^{s+1} - B^s}{\Delta t} + \nabla \times (v^s \times B^s) = 0.
\end{cases}
\]
\[ \text{(3.6e)} \]

where \( K_Q^s = \langle n^2 Q^s \rangle \) and
\[
\begin{align*}
(S_{re})^{s+1} &= \varepsilon \sigma_s \left( (T^{s+1})^4 - 4\pi J^{s+1} \right) + 4\pi (\varepsilon^3 \sigma_s - \varepsilon \sigma_s) \frac{v^{s+1}}{c} \left[ \frac{c}{3} R^{s+1} - v^{s+1} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q^s \right) \right], \\
(S_{rp})^{s+1} &= -4\pi (\varepsilon^3 \sigma_s + \varepsilon^2 \sigma_a) \left[ \frac{c}{3} R^{s+1} - v^{s+1} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q^s \right) \right] - \frac{c^2 v^{s+1}}{c} \sigma_a ((T^{s+1})^4 - 4\pi J^{s+1}).
\end{align*}
\]

The zeroth and first moment equations of (3.6a) are
\[
\begin{cases}
\frac{J^{s+1} - J^s}{\Delta t} + \frac{c}{3} \nabla \cdot R^{s+1} = \frac{c}{4\pi \varepsilon} (S_{re})^{s+1}, \\
\varepsilon^2 \frac{R^{s+1} - R^s}{3c \Delta t} + \frac{c}{3} \nabla \cdot J^{s+1} + \varepsilon \nabla \cdot K_Q^s = \frac{(S_{rp})^{s+1}}{4\pi}.
\end{cases}
\]
\[ \text{(3.7a, 3.7b)} \]

We first update \( \rho, B \) by (3.6b), (3.6e) and then solve (3.6c), (3.6d) and (3.7) to get \( J, R, v, T \). \( Q^{s+1} \) can then be updated implicitly by equation (3.6a), and we get the \( I^{s+1} \) by using (3.1).

**The diffusion limit of (3.7):** Then we will show the AP property of the semi-discretization (3.7). From (3.7b),
\[
R^{s+1} = \frac{4v^{s+1} J^{s+1}}{c} - \frac{\nabla \cdot J^{s+1}}{\sigma_s} + O(\varepsilon).
\]
\[ \text{(3.8)} \]
Multiplying equation (3.7a) by $4\pi P_0$, and adding it up with equation (3.6d), the terms on the right hand sides cancel. By using (3.8), and sending $\varepsilon \to 0$ in $4\pi P_0 \times (3.7a) + (3.6d)$ yields

$$\frac{a}{\Delta t} \left[ (\rho T)^{s+1} - (\rho T)^s \right] + \frac{\rho^{s+1} ((v^s)^2 - \rho^s (v^s)^2)}{2 \Delta t} + \frac{(B^{s+1})^2 - (B^s)^2}{2 \Delta t} + 4\pi P_0 J^{s+1} - J^s$$

$$+ \nabla \cdot \left[ (E^s + (P^s)^*) v^s - B^s (B^s \cdot v^s) + \frac{16 \pi P_0}{3} v^{s+1} J^{s+1} \right] = \nabla \cdot \left( \frac{4 \pi c P_0}{3 \sigma_e} \nabla J^{s+1} \right).$$

(3.9)

This is a semi-discretization for (2.10c). Then multiplying equation (3.7b) by $4\pi P_0$, and adding it to equation (3.6c), sending $\varepsilon \to 0$, formally one gets

$$\frac{(\rho v)^{s+1} - (\rho v)^s}{\Delta t} + \nabla \cdot (\rho^s v^s - B^s B^s + (P^s)^*) = - \frac{4\pi P_0}{3} \nabla \cdot J^{s+1}.$$  

(3.10)

This is a semi-discretization for (2.10b). Sending $\varepsilon \to 0$ in equation (3.7a), yields

$$4\pi \frac{J^{s+1} - J^s}{\Delta t} + \frac{4\pi c}{3} \nabla \cdot R^{s+1} = c\sigma_a ((T^{s+1})^4 - 4\pi J^{s+1}) - 4\pi \sigma_a \frac{v^{s+1}}{c} \left( \frac{c}{3} R^{s+1} - \frac{4}{3} v^{s+1} J^{s+1} \right),$$

(3.11)

using (3.8) in (3.11), we get

$$4\pi \frac{J^{s+1} - J^s}{\Delta t} + \frac{16\pi}{3} \nabla \cdot (v^{s+1} J^{s+1}) - \nabla \cdot \left( \frac{4\pi c}{3\sigma_s} \nabla J^{s+1} \right) = c\sigma_a ((T^{s+1})^4 - 4\pi J^{s+1}) + \frac{4\pi}{3} v^{s+1} \nabla \cdot J^{s+1},$$

(3.12)

which is a semi-discretization (2.10d).

3.3. The time discretization for the equilibrium regime. We substitute the decomposition in (3.1) into the RMHD system (2.11), and the time discretization of (2.11) is same with (3.6) except the RTE and source terms ($S_{te}$)_{s+1} and ($S_{rp}$)_{s+1}, which read:

$$\frac{J^{s+1} - J^s}{\Delta t} + e n \frac{R^{s+1} - R^s}{\Delta t} + \varepsilon \frac{Q^{s+1} - Q^s}{\Delta t} + \frac{c}{\varepsilon} n \nabla \cdot J^{s+1} + c n \nabla \cdot (n R^{s+1} + Q^s) = \frac{c\sigma_a}{\varepsilon^2} \left( \frac{(T^{s+1})^4}{4\pi} - J^{s+1} \right)$$

$$- \left( \frac{c\sigma_a}{\varepsilon} + c e \sigma_s \right) \left( n R^{s+1} + Q^{s+1} \right) - \frac{2}{3} \varepsilon^2 \sigma_s v^{s+1} R^{s+1} - (\sigma_a - \varepsilon^2 \sigma_s) \frac{v^{s+1} \cdot v^{s+1}}{c} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q \right)$$

$$+ 3 \frac{\sigma_a}{\varepsilon} n v^{s+1} \left( \frac{(T^{s+1})^4}{4\pi} - J^{s+1} \right) + n v^{s+1} \left( \frac{\sigma_a}{\varepsilon} + e \sigma_s \right) \left( 4 J^{s+1} + \varepsilon (n R^{s+1} + Q^s) \right),$$

(3.13)

and

$$(S_{te})^{s+1} = \frac{\sigma_a}{\varepsilon} ((T^{s+1})^4 - 4\pi J^{s+1}) + 4\varepsilon (\sigma_a - e^3 \sigma_s) \frac{v^{s+1}}{c^2} \left[ \frac{c}{3} R^{s+1} - v^{s+1} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q \right) \right],$$

(3.14)

$$(S_{rp})^{s+1} = - \frac{4\pi (e^2 \sigma_s + \sigma_a)}{c} \left[ \frac{c}{3} R^{s+1} - v^{s+1} \left( \frac{4}{3} J^{s+1} + \varepsilon K_Q \right) \right] - \frac{v^{s+1}}{c} \sigma_a ((T^{s+1})^4 - 4\pi J^{s+1}).$$

(3.15)

Moreover, the procedure of solving the equilibrium case is the same as for (3.6).

The diffusion limit of the equilibrium regime: The derivation of the equilibrium diffusion limit is similar to the non-equilibrium case, but requires additional analysis for the zeroth moment of equation (3.13). Sending $\varepsilon \to 0$ in the zeroth moment equation of (3.13), one gets

$$\sigma_a ((T^{s+1})^4 - 4\pi J^{s+1}) + O(\varepsilon^2) = 0,$$

which implies

$$4\pi J^{s+1} = (T^{s+1})^4 + O(\varepsilon^2).$$
Therefore, (3.9) and (3.10) in the equilibrium regime become
\[\frac{a(\rho T)^{t+1} - (\rho T)^t}{\Delta t} + \frac{\rho^{t+1}(v^t+1)^2 - \rho^t(v^t)^2}{2\Delta t} + \frac{(B^{t+1})^2 - (B^t)^2}{2\Delta t} + \frac{P_0}{\Delta t} \left( (T^{t+1})^4 - (T^t)^4 \right)\]
+ \nabla \cdot \left( (E^t + (P^t)^*) v^t - B^t (B^t \cdot v^t) + \frac{4P_0}{3} v^{t+1} (T^{t+1})^4 \right) = \nabla \cdot \left( \frac{4\pi c P_0}{3\sigma_a} \nabla (T^{t+1})^4 \right),
\]
\[\frac{(p\nu)^{t+1} - (p\nu)^t}{\Delta t} + \nabla \cdot (\rho^t v^t - B^t B^t) = -\frac{P_0}{3\sigma_a} \nabla \cdot (T^{t+1})^4,\]
which gives a semi-discretization of system (2.14).

4. THE FULL DISCRETIZATION FOR THE NON-EQUILIBRIUM REGIME

For the ease of exposition, we will explain our spatial discretion in 1D. That is, \(x \in [0, L], n \in [-1, 1]\), and \(\langle f(n) \rangle = \frac{1}{2} \int_{-1}^{1} f(n)dn\). Recall the RMHD for the non-equilibrium case in the slab geometry:

\[\begin{align*}
\partial_t I + \frac{c}{\varepsilon} \partial_x I &= c\sigma_a \left( \frac{T^4}{4\pi} - I \right) + \frac{\sigma_x}{c\varepsilon} (J - I) + 3\varepsilon n v_x \sigma_a \left( \frac{T^4}{4\pi} - J \right) + n v_x \left( \varepsilon \sigma_a + \frac{\sigma_x}{\varepsilon} \right) (I + 3J) \\
-2\frac{\sigma_x v_x}{c} J &= \frac{1}{c} \partial_x \left\{ \frac{\varepsilon^2 \varepsilon_s - \varepsilon_s}{c} \left( 2\sigma_x v_x \cdot I - \varepsilon^2 \sigma_a - \sigma_s \right) \left( v_x \cdot I - \varepsilon^2 \sigma_a - \sigma_s \right) \right\}, \tag{4.1a}
\end{align*}\]
\[\begin{align*}
\partial_t \rho + \partial_x (\rho v_x) &= 0, \tag{4.1b}
\partial_t (\rho v_y) + \partial_x (\rho v_x v_y - B_x B_y) &= 0, \tag{4.1c}
\partial_t (\rho v_z) + \partial_x (\rho v_x v_z - B_x B_z) &= 0, \tag{4.1d}
\partial_t \left( a\rho T + \frac{\rho v^2 + B^2}{2} \right) + \partial_x [(E + P^*) v_x - (B \cdot v) B_x] &= -\frac{c}{\varepsilon} \partial_x S_{\text{re}}, \tag{4.1e}
\partial_t B_y + \partial_x (B_y v_x - B_x v_y) &= 0, \tag{4.1f}
\partial_t B_z + \partial_x (B_z v_x - B_x v_z) &= 0, \tag{4.1g}
\end{align*}\]

where
\[S_{\text{re}} = \frac{\varepsilon_s}{c} \left( T^4 - 2\pi \int_{-1}^{1} Idn \right) + \frac{2\pi (\varepsilon^2 \varepsilon_s - \varepsilon_s)^2}{c} \left[ \frac{c}{\varepsilon} \int_{-1}^{1} nIdn - \left( v_x \int_{-1}^{1} Idn + v_x \int_{-1}^{1} n^2 Idn \right) \right],\]
\[S_{\text{rp}} = -\frac{2\pi (\sigma_s + 2\sigma_a)}{c} \left[ \frac{c}{\varepsilon} \int_{-1}^{1} nIdn - \left( v_x \int_{-1}^{1} Idn + v_x \int_{-1}^{1} n^2 Idn \right) \right] + \frac{\varepsilon_s}{c} \int_{-1}^{1} nIdn],\]
and \(v_x, v_y\) and \(v_z\) are fluid velocity in the \(x-, y-,\) and \(z-\)directions, respectively. \(B_x, B_y\) and \(B_z\) are magnetic flux in the \(x-, y-,\) and \(z-\)directions, respectively. The boundary condition becomes
\[I(t, 0, n) = b_L(t, n), \quad \text{for } n > 0; \quad I(t, L, n) = b_R(t, n), \quad \text{for } n < 0. \tag{4.2}\]

Higher dimensions can be treated in the dimension by dimension manner. Let \([a, b]\) be the computational domain, \(\Delta x = (b - a)/N_x\), and we consider the uniform mesh as follows
\[x_{i-\frac{1}{2}} = a + (i - 1) \Delta x, \quad i = 1, 2 \cdots, N_x + 1,\]
and let
\[x_{\frac{1}{2}} = a < x_1 < x_{\frac{3}{2}} < \cdots < x_{i-\frac{1}{2}} < x_i < x_{i+\frac{1}{2}} < \cdots < x_{N_x} < x_{N_x+\frac{1}{2}} = b,\]
\[x_i = \left( x_{i-\frac{1}{2}} + x_{i+\frac{1}{2}} \right)/2, \quad \text{for } i = 1, \cdots, N_x.\]

To get a consistent stencil in spatial discretization, we use the unified gas kinetic scheme (UGKS) for spatial discretization [22]. Other space discretization that is AP can be applied as well. The most crucial point is that the space discretization of the MHD system has to be consistent with that of RTE.
4.1. A finite volume approach. UGKS is a finite volume method, integrating RMHD system (4.1) over \([t, t+\frac{\Delta t}{2}]\) and \([x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]\) gives

\[
\frac{J_{i}^{s+1} - J_{i}^{s}}{\Delta t} + \varepsilon n \frac{R_{i}^{s+1} - R_{i}^{s}}{\Delta t} + \varepsilon \frac{Q_{i}^{s+1} - Q_{i}^{s}}{\Delta t} + \frac{1}{\Delta x}(\zeta_{i+\frac{1}{2}} - \zeta_{i-\frac{1}{2}}) =
\]

\[
\left(\varepsilon \sigma_{a} \frac{(T_{i}^{s+1})^{4}}{4\pi} - J_{i}^{s+1}\right) - \frac{(\varepsilon \sigma_{a} + \frac{c}{\varepsilon})}{\varepsilon}(nR_{i}^{s+1} + Q_{i}^{s+1}) + G_{i},
\]

(4.3a)

\[
\frac{\rho_{i}^{s+1} - \rho_{i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{i+\frac{1}{2}} - F_{i-\frac{1}{2}}) = 0,
\]

(4.3b)

\[
\frac{(\rho v_{x})_{i}^{s+1} - (\rho v_{x})_{i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{2,i+\frac{1}{2}} - F_{2,i-\frac{1}{2}}) = -\mathcal{P}_{0}(S_{x})_{i}^{s+1},
\]

(4.3c)

\[
\frac{(\rho v_{x})_{i}^{s+1} - (\rho v_{y})_{i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{3,i+\frac{1}{2}} - F_{3,i-\frac{1}{2}}) = 0,
\]

(4.3d)

\[
\frac{(\rho v_{x})_{i}^{s+1} - (\rho v_{y})_{i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{4,i+\frac{1}{2}} - F_{4,i-\frac{1}{2}}) = 0,
\]

(4.3e)

\[
a(\rho T)_{i}^{s+1} - (\rho T)_{i}^{s} = \frac{(\rho v^{2} + B^{2})_{i}^{s+1} - (\rho v^{2} + B^{2})_{i}^{s}}{2\Delta t} + \frac{1}{\Delta x}(F_{5,i+\frac{1}{2}} - F_{5,i-\frac{1}{2}}) = -\frac{c}{\varepsilon}\mathcal{P}_{0}(S_{r})_{i}^{s+1},
\]

(4.3f)

\[
\frac{B_{y,i}^{s+1} - B_{y,i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{6,i+\frac{1}{2}} - F_{6,i-\frac{1}{2}}) = 0,
\]

(4.3g)

\[
\frac{B_{z,i}^{s+1} - B_{z,i}^{s}}{\Delta t} + \frac{1}{\Delta x}(F_{7,i+\frac{1}{2}} - F_{7,i-\frac{1}{2}}) = 0,
\]

(4.3h)

where \(G_{i}, (\mathcal{S}_{x})_{i}^{s+1}\) and \((\mathcal{S}_{x})_{i}^{s+1}\) are

\[
G_{i} = 3\varepsilon \sigma_{a,i} \nu_{x,i} \frac{(T_{i}^{s+1})^{4}}{4\pi} - J_{i}^{s+1} + n_{l} \frac{(\varepsilon \sigma_{a,i} + \frac{\sigma_{a,i}}{\varepsilon})}{c} \left(4J_{i}^{s+1} + \varepsilon(nR_{i}^{s+1} + Q_{i}^{s})\right)
\]

\[-2\frac{3\sigma_{a,i}^{2}}{c} R_{i}^{s+1} - \frac{(\varepsilon \sigma_{a,i} - \sigma_{a,i}) (\nu_{x,i}^{s+1})^{2}}{c} \left(4J_{i}^{s+1} + \varepsilon K_{Q,i}\right),
\]

\[
(\mathcal{S}_{x})_{i}^{s+1} = 4\pi \varepsilon \sigma_{a,i} \frac{(T_{i}^{s+1})^{4}}{4\pi} - J_{i}^{s+1} + 4\pi (\varepsilon \sigma_{a,i} - \varepsilon \sigma_{a,i}) \nu_{x,i}^{s+1} \left(\frac{4}{3} J_{i}^{s+1} + \varepsilon K_{Q,i}\right),
\]

\[
(\mathcal{S}_{x})_{i}^{s+1} = -\frac{4\pi (\sigma_{a,i} + \varepsilon^{2} \sigma_{a,i})}{c} \left[\varepsilon \frac{R_{i}^{s+1} - \nu_{x}^{s+1}}{c} \left(\frac{4}{3} J_{i}^{s+1} + \varepsilon K_{Q,i}\right)\right] + 4\pi \frac{c^{2}}{\varepsilon} \sigma_{a,i} \nu_{x,i}^{s+1} \left(\frac{(T_{i}^{s+1})^{4}}{4\pi} - J_{i}^{s+1}\right).
\]

Here the numerical fluxes \(F_{s}, i=\frac{1}{2}\) at the interface uses Roe’s Riemann solver [29], based on the piecewise linear reconstruction. At last, we discuss the microscopic flux \(\zeta\) defined at the interface \(x_{i+\frac{1}{2}}\) in (4.3a). In [22], all the terms of the microscopic flux are treated explicitly, in this paper all the terms except the initial value and \(K_{Q}\) are treated implicitly, and the processes of UGKS are detailed in Appendix A.

With the expressions (A.3), (A.4) and (A.6), the numerical flux \(\zeta_{i+\frac{1}{2}}\) is

\[
\zeta_{i+\frac{1}{2}} = A_{i+\frac{1}{2}} \left(\frac{I_{i+\frac{1}{2}}^{s+1} + \Omega_{i+\frac{1}{2}}^{s+1} - \Omega_{i+\frac{1}{2}}^{s+1}}{4\pi} + C_{i+\frac{1}{2}}^{s+1} n_{l} J_{i+\frac{1}{2}}^{s+1} + \frac{C_{i+\frac{1}{2}}^{s+1} n_{l} (T_{i+\frac{1}{2}}^{s+1})^{4}}{4\pi} + F_{i+\frac{1}{2}}^{s+1} n_{l} \hat{G}_{i+\frac{1}{2}}\right)
\]

\[
+ D_{i+\frac{1}{2}}^{s+1} n^{2} \left(\delta_{x}(J_{i+\frac{1}{2}}^{s+1})^{2} \Omega_{i+\frac{1}{2}}^{s+1} + \delta_{x}(J_{i+\frac{1}{2}}^{s})^{2} \Omega_{i+\frac{1}{2}}^{s} - \delta_{x}(J_{i+\frac{1}{2}}^{s+1}) \Omega_{i+\frac{1}{2}}^{s+1} + \delta_{x}(J_{i+\frac{1}{2}}^{s}) \Omega_{i+\frac{1}{2}}^{s}\right)
\]

\[
+ D_{i+\frac{1}{2}}^{s+1} n^{2} \left(\delta_{x}(J_{i+\frac{1}{2}}^{s+1})^{2} \Omega_{i+\frac{1}{2}}^{s+1} + \delta_{x}(J_{i+\frac{1}{2}}^{s})^{2} \Omega_{i+\frac{1}{2}}^{s} - \delta_{x}(J_{i+\frac{1}{2}}^{s+1}) \Omega_{i+\frac{1}{2}}^{s+1} + \delta_{x}(J_{i+\frac{1}{2}}^{s}) \Omega_{i+\frac{1}{2}}^{s}\right)
\]

\[
= I_{i+\frac{1}{2}}^{s-1} = I_{i+1}^{s} + \frac{\Delta x}{2} \delta_{x} I_{i+1}^{s},
\]

(4.4)
Moreover, the coefficients in the numerical flux are given by:

\[
A = \frac{c}{\Delta t \varepsilon \mu} (1 - e^{-\mu \Delta t}), \\
C^1 = \frac{c^2 \sigma_s}{\Delta t \varepsilon^3 \mu} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right), \\
C^2 = \frac{c^2 \sigma_a}{\Delta t \varepsilon \mu} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right), \\
D^1 = -\frac{c^3 \sigma_a}{\Delta t \varepsilon^2 \mu^2} \left( \Delta t (1 + e^{-\mu \Delta t}) - \frac{2}{\mu} (1 - e^{-\mu \Delta t}) \right), \\
D^2 = -\frac{c^3 \sigma_a}{\Delta t \varepsilon^2 \mu^2} \left( \Delta t (1 + e^{-\mu \Delta t}) - \frac{2}{\mu} (1 - e^{-\mu \Delta t}) \right), \\
F = \frac{c}{\Delta t \varepsilon \mu} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right),
\]

with \( \mu = \frac{c^2 \sigma_a + c \sigma_s}{\varepsilon^2} \). For reader’s convenience, the processes of UGKS are detailed in Appendix A.

To obtain a scheme that can update the quantities \( J, R, T \) and \( v_x \), the zeroth moment and first moment of velocity field \( n \) for (4.3a) are needed. Integrating equation (4.3a) for \( n \) from -1 to 1, and multiplying the both sides by \( 4\pi \), one can obtain

\[
4\pi \frac{J^{s+1}_i - J^s_i}{\Delta t} + \frac{2\pi}{\Delta x} \int_{-1}^1 \tilde{v}_{1/2} - \tilde{v}_{-1/2} \, dn = \frac{c}{\varepsilon} (\tilde{S}_{re})^{s+1}_i,
\]

where

\[
\int_{-1}^1 \tilde{v}_{1/2} \, dn = \int_{-1}^1 A_{i,1/2} n \left( I_{i,1/2+}^s \mathbb{1}_{n>0} + I_{i,1/2-}^s \mathbb{1}_{n<0} \right) \, dn + \frac{2D^1_{i+1/2}}{\Delta x} \left( J^{s+1}_{i+1/2} - J^{s+1}_i \right) + \frac{D^2_{i+1/2}}{\Delta x} \left( (T^{s+1})^4_i - (T^{s+1})^4_{i+1/2} \right) \\
+ F_{i,1/2} \left[ 2\varepsilon \sigma_a, i, 1/2 v^{s+1}_{x,i+1/2} \left( \frac{(T^{s+1})^4_{i+1/2}}{4\pi} - J^{s+1}_{i+1/2} \right) + v^{s+1}_{x,i+1/2} \frac{\sigma_s, i, 1/2 + \varepsilon^2 \sigma_a, i, 1/2}{\varepsilon} \right].
\]

Multiplying equation (4.3a) by \( n \), then integrating it for \( n \) from -1 to 1, and multiplying the both sides by \( 4\pi \), one can obtain

\[
\frac{4\pi \varepsilon}{3} \frac{R^{s+1}_i - R^s_i}{\Delta t} + \frac{2\pi}{\Delta x} \int_{-1}^1 n \left( \tilde{v}_{1/2} - \tilde{v}_{-1/2} \right) \, dn = \frac{c}{\varepsilon} (\tilde{S}_{rp})^{s+1}_i,
\]

where

\[
\int_{-1}^1 n \tilde{v}_{1/2} \, dn = \int_{-1}^1 A_{i,1/2} n^2 \left( I_{i,1/2+}^s \mathbb{1}_{n>0} + I_{i,1/2-}^s \mathbb{1}_{n<0} \right) \, dn + \frac{C^1_{i+1/2}}{3} \left( J^{s+1}_{i+1/2} + J^{s+1}_i \right) + \frac{C^2_{i+1/2}}{12\pi} \left( (T^{s+1})^4_{i+1/2} + (T^{s+1})^4_i \right) \\
+ F_{i,1/2} \left[ v^{s+1}_{x,i+1/2} \left( \varepsilon^2 \sigma_a, i, 1/2 + \sigma_s, i, 1/2 \right) \left( \frac{2}{3} R^{s+1}_i + \int_{-1}^1 n^3 Q^{s}_{i+1/2} \, dn \right) - \frac{4}{9} \sigma_s, i, 1/2 v^{s+1}_{x,i+1/2} R^{s+1}_{i+1/2} \\
- \frac{2(\varepsilon^2 \sigma_a, i, 1/2 - \sigma_s, i, 1/2)}{3c} \left( v^{s+1}_{x,i+1/2} \right)^2 \left( \frac{4}{3} J^{s+1}_{i+1/2} + \varepsilon K^{s}_{Q,i+1/2} \right) \right].
\]

Coupling equations (4.7), (4.8), (4.3c) and (4.3f) as a system and solving the system, quantities \( J, R, T \) and \( v_x \) can be updated. Finally, quantity \( Q \) can be updated by equation (4.3a), and the new \( I \) can be given by using (3.1).
4.2. The diffusion limit of (4.3c)–(4.8). Firstly, assuming $\sigma_\alpha$ and $\sigma_s$ are positive, as $\varepsilon \to 0$, the leading order of the coefficients in the numerical flux (4.4) are

$$A(\Delta t, \varepsilon, c, \sigma_\alpha, \sigma_s) = 0 + O(\varepsilon),$$

$$\varepsilon C^1(\Delta t, \varepsilon, c, \sigma_\alpha, \sigma_s) = c + O(\varepsilon), \quad \varepsilon C^2 = 0 + O(\varepsilon),$$

$$D^1 = -\frac{c}{\sigma_s} + O(\varepsilon), \quad D^2 = 0 + O(\varepsilon),$$

$$\frac{1}{\varepsilon} F = \frac{1}{\sigma_s} + O(\varepsilon).$$

This means the zero moment and the first moment of the numerical flux, as $\varepsilon \to 0$, have the following limit:

$$\int_{-1}^{1} \hat{\gamma}_{i+\frac{1}{2}} dn \rightarrow \frac{8}{3} v_{s,i+\frac{1}{2}}^s J_{i+\frac{1}{2}}^s - \frac{2c}{3\sigma_s,i+\frac{1}{2}} J_{i+\frac{1}{2}}^s - J_{i+\frac{1}{2}}^s + J_{i+\frac{1}{2}}^s,$$  \hspace{1cm} (4.9)

$$\varepsilon \int_{-1}^{1} n \hat{\gamma}_{i+\frac{1}{2}} dn \rightarrow \frac{c}{3} (J_{i+1}^s + J_{i+1}^s).$$  \hspace{1cm} (4.10)

Multiplying equation (4.7) by $P_0$, and adding it up with equation (4.3f), the terms on the right hand sides cancel. By sending $\varepsilon \to 0$ and using (4.9) yields

$$\frac{a(\rho T)^{s+1}_i - (\rho T)^s_i}{\Delta t} + \frac{\rho c^4}{2\Delta t} + \frac{4\pi P_0 J_{i+1}^s - J_i^s}{\Delta x} + \frac{1}{\Delta x} (F_{i+1}^s - F_{i}^s) + \frac{16\pi P_0 v_{s,i+\frac{1}{2}}^s J_{i+\frac{1}{2}}^s - v_{s,i-\frac{1}{2}}^s J_{i-\frac{1}{2}}^s}{3\Delta x} = 0.$$

This is a fully discretization for (2.10c). Then multiplying equation (4.8) by $\varepsilon P_0$, and adding it to equation (4.3c), sending $\varepsilon \to 0$ and using (4.10), one obtains

$$\frac{\rho v_x)^{s+1}_i - (\rho v_x)^s_i}{\Delta t} + \frac{1}{\Delta x} (F_{i+1}^s - F_{i}^s) + \frac{2\pi P_0 J_{i+1}^s - J_i^s}{3\Delta x} = 0.$$

This is a fully discretization for (2.10b). Sending $\varepsilon \to 0$ in equation (4.8) and using (4.10) gives

$$R_i^{s+1} = \frac{4}{c} v_{s,i+\frac{1}{2}}^s J_{i+\frac{1}{2}}^s - J_{i+\frac{1}{2}}^s - J_{i+\frac{1}{2}}^s,$$  \hspace{1cm} (4.13)

using (4.13) in (4.7) and sending $\varepsilon \to 0$, one gets

$$4\pi \frac{J_{i+1}^s - J_i^s}{\Delta t} = 4\pi \left[ \frac{c}{3\sigma_{s}^{i+\frac{1}{2}}} \frac{J_{i+1}^s - J_i^s}{\Delta x} - \frac{c}{3\sigma_{s,i-\frac{1}{2}}^{i+\frac{1}{2}}} \frac{J_{i+1}^s - J_i^s}{\Delta x} \right]$$

$$+ \frac{16\pi v_{s,i+\frac{1}{2}}^s J_{i+\frac{1}{2}}^s - v_{s,i-\frac{1}{2}}^s J_{i-\frac{1}{2}}^s}{3\Delta x} = c\sigma_{s,i} \left( (T_{i+1}^s)^4 - 4\pi J_i^s \right) - \frac{2\pi P_0 J_{i+1}^s - J_i^s}{3\Delta x},$$

which is a fully discretization for (2.10d).

4.3. Boundary conditions. In this section, the numerical fluxes in the system (4.3c)–(4.8) under the boundary condition (4.2) are considered. The construction of the flux on the right boundary is similar to the construction on the left boundary, for which we only consider the left boundary case. At the left boundary, the integral representation of the radiative intensity $I$ (A.3) reads:

$$I_{\frac{1}{2}}(t) = \begin{cases} b_L, & \text{if } n > 0, \\
\frac{t}{t_c} e^{-\frac{1}{2}(t-t_s)} I \left( t_s, x_{\frac{1}{2}} + \frac{c \sigma}{\varepsilon} (t-t_s) \right) + \frac{1-e^{-\frac{1}{2}(t-t_s)}}{\mu_{\frac{1}{2}}} G_{\frac{1}{2}} \\
+ \frac{t}{t_c} e^{-\frac{1}{2}(t-t_s)} \left( \frac{c \sigma}{\varepsilon} J \left( z, x_{\frac{1}{2}} - \frac{c \sigma}{\varepsilon} (t-t_s) \right) + \frac{c \sigma}{4\pi} T^4 \left( z, x_{\frac{1}{2}} - \frac{c \sigma}{\varepsilon} (t-t_s) \right) \right) d\tau, & \text{if } n < 0. \end{cases}$$

\hspace{1cm} (4.15)
According to the approximation (A.4) and (A.6), the reconstruction of \( I \) for \( n < 0 \) and \( x > x_\frac{1}{2} \) at the left boundary can be written as:

\[
I(t_s, x, n) = I_0^1,
\]

and the reconstruction of \( J \) for \( t \) in the interval \([t_s, t_{s+1}]\):

\[
J(t, x) = J_\frac{1}{2}^{s+1} + \delta_x J^{s+1,-}_\frac{1}{2} (x - x_\frac{1}{2}),
\]

where \( J_\frac{1}{2}^{s+1} = \frac{1}{2} (b_L + J_{1}^{s+1}) \) and \( \delta_x J^{s+1,-}_\frac{1}{2} = \frac{J_{1}^{s+1} - J_{1}^{s+1}}{\Delta x/2} \). Then the numerical flux at the left boundary reads:

\[
\zeta_\frac{1}{2} = \frac{cn}{\varepsilon} b_L \Theta_{n>0} + A_\frac{1}{2} n I^1_{n<0} + C_1 \frac{n J^{s+1}_\frac{1}{2} \Theta_{n<0}}{2} + \frac{C^2}{4\pi} n (T^{s+1}_1)^4 \Theta_{n<0} + F_\frac{1}{2} n \hat{G}_\frac{1}{2} \Theta_{n<0} + D_\frac{1}{2} n^2 \delta_x J^{s+1,-}_\frac{1}{2} \Theta_{n<0} + \frac{D^2}{4\pi} n^2 \delta_x (T^{s+1,-}_1)^4 \Theta_{n<0},
\]

which indicates

\[
\int_{-1}^{1} \zeta_\frac{1}{2} dn = \int_{-1}^{1} \left( \frac{cn}{\varepsilon} b_L \Theta_{n>0} + A_\frac{1}{2} n I^1_{n<0} \right) dn - \frac{1}{2} \left( \frac{C^2}{2} (J_{1}^{s+1} + b_L) + \frac{C^2}{8\pi} ((T^{s+1}_1)^4 + (T^{s+1}_L)^4) \right) \]

\[
- \frac{F_\frac{1}{2} \hat{G}_\frac{1}{2}}{2} + \frac{1}{3\Delta x} \left( D_\frac{1}{2} (J_{1}^{s+1} - b_L) + \frac{D^2}{4\pi} ((T^{s+1}_1)^4 - (T^{s+1}_L)^4) \right),
\]

here \( T^{s+1}_L \) is the material temperature at the left boundary, and

\[
\int_{-1}^{1} n \zeta_\frac{1}{2} dn = \int_{-1}^{1} \left( \frac{cn}{\varepsilon} b_L \Theta_{n>0} + A_\frac{1}{2} n^2 I^1_{n<0} \right) dn - \frac{1}{3} \left( \frac{C^2}{2} (J_{1}^{s+1} + b_L) + \frac{C^2}{8\pi} ((T^{s+1}_1)^4 + (T^{s+1}_L)^4) \right) \]

\[
+ \frac{F_\frac{1}{2} \hat{G}_\frac{1}{2}}{3} - \frac{1}{3\Delta x} \left( D_\frac{1}{2} (J_{1}^{s+1} - b_L) + \frac{D^2}{4\pi} ((T^{s+1}_1)^4 - (T^{s+1}_L)^4) \right).
\]

To summarize, we have the following one time step update of the fully discrete version of RMHD.

**Algorithm 1:** one step of fully discrete update for RMHD

**Input:** \( \rho_i^0, v_{x,i}^0, v_{y,i}^0, v_{z,i}^0, T_i^0, B_{y,i}^0, B_{z,i}^0, I_i^0, J_i^0 \) (\( J_i^0 = \langle I_i^0 \rangle \))

**Output:** \( \rho_i^{s+1}, v_{x,i}^{s+1}, v_{y,i}^{s+1}, v_{z,i}^{s+1}, T_i^{s+1}, B_{y,i}^{s+1}, B_{z,i}^{s+1}, I_i^{s+1}, J_i^{s+1} \) (\( J_i^{s+1} = \langle I_i^{s+1} \rangle \))

1. obtain \( \rho_i^{s+1}, v_{x,i}^{s+1}, v_{y,i}^{s+1}, v_{z,i}^{s+1}, T_i^{s+1}, B_{y,i}^{s+1}, B_{z,i}^{s+1}, I_i^{s+1}, J_i^{s+1} \) from (4.3b), (4.3d), (4.3e), (4.3g) and (4.3h);
2. obtain \( R_i^s, Q_i^s \) from (3.2) and (3.1);
3. get \( J_i^{s+1}, T_i^{s+1}, v_{x,i}^{s+1}, B_{y,i}^{s+1}, B_{z,i}^{s+1} \) from the system coupled by (4.3c), (4.3f), (4.7) and (4.8);
4. get \( Q_i^{s+1} \) from equation (4.3a) and \( Q_i^s \) replaced by \( Q_i^{s+1} \) and \( K_{Q,i}^s \) replaced by \( K_{Q,i}^{s+1} \);
5. obtain \( I_i^{s+1} \) from (3.1).

5. Numerical Examples

In this section, we conduct numerical experiments to test the performance of our proposed method. The examples cover both optically thin \( \varepsilon \approx O(1) \) and optically thick \( \varepsilon \ll 1 \) cases, as well as the radiation shock problem. In all the numerical examples, we use \( S_8 \) discrete ordinate method in the angle space.
5.1. Example 1. In this example, we will test an ideal MHD shock tube problem as in Section V in [2], where \( \mathcal{P}_0 = 0 \) in (2.2). In this case, the radiation does not affect the fluid, but the fluid provides source for radiation. The computational domain is \([-1, 1]\) and the initial data is given by

\[
(\rho, v_x, v_y, v_z, B_y, B_z, p)(x, 0) = \begin{cases} 
(1, 0, 0, 0, 1, 0, 1), & x < 0, \\
(0.125, 0, 0, 0, -1, 0, 0.1), & x > 0.
\end{cases}
\]  

(5.1)

The magnetic intensity in the \( x \) direction \( B_x = 0.75 \), the ideal gas constant \( R_{\text{ideal}} = 1 \) and adiabatic index for an ideal gas \( \gamma = 2 \), the absorption collision cross-section \( \sigma_a(x) = 1/3 \), the scatter collision cross-section \( \sigma_s(x) = 1/3 \), \( c = 0.1 \) and \( \varepsilon = 10^{-5} \) in the RMHD system (2.2). The exact solutions at time \( t > 0 \) involve two fast rarefaction waves, a slow compound wave, a contact discontinuity, and a slow shock. Fig. 1 displays the numerical solutions at \( t = 0.2 \) obtained by our method using 800 uniform grids. The reference solution is computed by Roe’s method shown in [29] with 4000 uniform grids. Moreover, the reference solution of \( J \) is solved using the diffusion limit equation (2.10) by the semi-implicit scheme (B.7) and (B.8). For all the schemes, the time step is \( \Delta t = 0.2 \Delta x \).

5.2. Example 2. The uniform accuracy and stability of the AP method at the equilibrium regime are tested in this example. The initial data is the same as in (5.1) in example 1, and the initial temperature and density fluxes are

\[
T(0, x) = p/(R_{\text{ideal}} \rho), \quad I(0, x, n) = \frac{T(0, x)^4}{4\pi}.
\]  

(5.2)

Moreover, we assume that \( \mathcal{P}_0 = 0.001 \), \( c = 0.1 \) in this example. The absorption collision cross-section \( \sigma_a \) and the scatter collision cross-section \( \sigma_s \) are chosen as \( \sigma_a(x) = \sigma_s(x) = 1/3 \).

**Accuracy.** The uniform convergence order of the diffusion limit system (2.14) and the RMHD system (2.11) of our AP scheme are given. In Fig. 3, we plot

\[
\text{error}_p = \|p_{\Delta x}(\cdot, t_{\text{max}}) - p_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1}, \quad \text{error}_v = \|p_{\Delta x}(\cdot, t_{\text{max}}) - p_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1},
\]

\[
\text{error}_{v_x} = \|v_{x,\Delta x}(\cdot, t_{\text{max}}) - (v_x)_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1}, \quad \text{error}_{v_y} = \|v_{y,\Delta x}(\cdot, t_{\text{max}}) - (v_y)_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1},
\]

\[
\text{error}_{B_y} = \|B_{y,\Delta x}(\cdot, t_{\text{max}}) - (B_y)_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1}, \quad \text{error}_T = \|T_{\Delta x}(\cdot, t_{\text{max}}) - T_{\Delta x/2}(\cdot, t_{\text{max}})\|_{l_1},
\]  

(5.3)

for the diffusion limit system (2.14) with decreasing \( \Delta x \) and \( t_{\text{max}} = 0.2 \). Then in Figs. 4, we plot the same errors for RMHD system (2.11) with decreasing \( \Delta x \) and \( t_{\text{max}} = 0.2 \) for different values of \( \varepsilon = 1, 10^{-1}, 10^{-3}, 10^{-5} \).

**Stability condition.** To check the stability, we choose \( \Delta t = C \Delta x \) with \( C \) being constant, and record the largest possible choice of \( C \) in Table 1 for different \( \varepsilon \) and \( \Delta x \). Uniform hyperbolic stability is observed numerically.

**Table 1.** Stability test for the RMHD system (2.11). Here we use \( \Delta t = C \Delta x \) and the largest possible \( C \) that stabilize the scheme are displayed.

5.3. Example 3. In the simulation of RMHD, it is a challenging task to produce accurate radiative shocks, especially in the optically thick regime. We test a range of the radiation-hydrodynamic shock problems presented in [20] in which several shocks are presented in the solution. For each of these shocks, we set $P_0 = 10^{-4}$, adiabatic index for an ideal gas $\gamma = 5/3$, absorption collision cross-section $\sigma_a = 1/3$, scatter
A SPATIAL-TEMPORAL ASYMPTOTIC PRESERVING SCHEME FOR RADIATION MAGNETOHYDRODYNAMICS

Figure 2. Comparison of J of our AP scheme and the reference solution obtained by semi-implicit solver (B.7)–(B.8) for RMHD system (2.2). Here $P_0 = 0$, $\varepsilon = 10^{-5}$, $t = 0.2$, $\Delta x = 1/800$, $\Delta t = 0.2\Delta x$ for both two schemes.

Figure 3. Plot of errors (5.3) for diffusion limit system (2.14) with decreasing $\Delta x = \frac{1}{100}$, $\frac{1}{200}$, $\frac{1}{400}$, $\frac{1}{800}$, $\frac{1}{1600}$. Here $\Delta t = 0.2\Delta x$.

collision cross-section $\sigma_s = 10^6$, $c = 3 \times 10^6$, $\varepsilon = 1$ in RMHD system (2.2), and the radiation temperature $T_r \equiv (4\pi J)^{0.25}$. Moreover, the computational domain is $[-0.02, 0.02]$ and the results at $t = 0.04$ are displayed. In this example, $\Delta x = 1/800$, $\Delta t = 0.2\Delta x$. In [20], the authors have obtained some semi-analytic solutions for the non-equilibrium diffusion limit system (2.10) at different Mach numbers, we compare the numerical results with the semi-analytic solutions obtained [20].

\[
(\rho, v_x, v_y, v_z, B_y, B_z, T, T_r) (x, 0) = \begin{cases} 
(1, 1.2, 0, 0, 0, 0, 1, 1), & x < 0, \\
(1.298088, 0.9244363, 0, 0, 0, 0, 1.194888, 1.194888), & x > 0,
\end{cases}
\]

(5.4)

\[
(\rho, v_x, v_y, v_z, B_y, B_z, T, T_r) (x, 0) = \begin{cases} 
(1, 2, 0, 0, 0, 0, 1, 1), & x < 0, \\
(2.287066, 0.87482876, 0, 0, 0, 0, 2.077223, 2.077223), & x > 0.
\end{cases}
\]

(5.5)

First of all, a Mach 1.2 shock is considered, which has no isothermal sonic point (ISP) but a hydrodynamic shock. The initial conditions are shown in (5.4). Fig. 7 compares our numerical results with the semi-analytic
solutions, in which we can see good agreement for all quantities, including density, velocity, material and radiation temperature. Due to the hydrodynamic shock, there exhibits discontinuities in the solution profiles of density, velocity and material temperature, and the maximum material temperature is bounded, since there is no ISP to drive it further.

At Mach 2, there are both a hydrodynamic shock and an ISP. The initial conditions are given in (5.5). Fig. 8 compares our numerical results with the semi-analytic solutions. One can see that our numerical results are in good agreement with the semi-analytic solutions. In Fig. 8, discontinuities can be seen in material density, velocity and material temperature due to the hydrodynamic shock. Moreover, the Zel’dovich spike can be observed in material temperature as in Fig. 8(c). The Zel’dovich spike is caused by the ISP embedded within the hydrodynamic shock, which drives up the material temperature at the shock front.

6. Conclusion and discussions

In this paper, we have introduced an AP scheme in both space and time for the RMHD system that couples the ideal MHD equations with a gray RTE, and two different scalings are considered, one results in an equilibrium diffusion limit system, while the other results in nonequilibrium. The main idea is to decompose the intensity into three parts, two parts correspond to the zeroth and first order moments, while
Figure 5. Comparison of the results of our AP scheme and the reference solution obtained by fully explicit scheme for RMHD system (2.11). Here $\varepsilon = 1$, $t = 0.2$, $\Delta x = 1/800$, $\Delta t = 0.2\Delta x$ for the AP scheme, and $\Delta x = 1/4000$, $\Delta t = 0.001\Delta x$ for the explicit solver.
Figure 6. Comparison of the results of our AP scheme and the reference solution obtained by the semi-implicit solver (B.7)–(B.8) for RMHD system (2.11). Here $\varepsilon = 10^{-5}$, $t = 0.2$, $\Delta x = 1/800$, $\Delta t = 0.2\Delta x$ for both two schemes.
the third part is the residual. The two macroscopic moments are treated implicitly while the residual is explicit. For the space discretization, we use Roe’s method in the Athena code to solve the convective part in the ideal MHD equations and the UGKS for the RTE. Numerical results are presented in the optically thick region and the radiative shock problem, which are compared to the semi-analytic solution to verify accuracy and asymptotic properties of our method.

It would be worthwhile to construct a second-order AP method for the radiation magnetohydrodynamics system. In the semi-implicit scheme, a simple time-integration method has been used. To obtain a second scheme, higher order IMEX time-integration method can be considered.

Figure 8. Comparison of the results using our AP scheme at time $t = 0.04$ and the semi-analytic solution for Mach number $M = 2$. For AP scheme, we use $\Delta x = 1/800$ and $\Delta t = 0.2\Delta x$.

Appendix A. The processes of UGKS for the non-equilibrium regime

Recall the RTE (4.1a) in the slab geometry, and integrating it over $[t_s, t_{s+1}]$ and $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$ gives

$$\frac{I_{i+1}^{s+1} - I_i^s}{\Delta t} + \frac{1}{\Delta x}(\zeta_{i+\frac{1}{2}} - \zeta_{i-\frac{1}{2}}) = c\sigma_{a,i} \left( \frac{(T_{i+1}^{s+1})^4}{4\pi} - I_{i}^{s+1} \right) + \frac{c\sigma_{s,i}}{\varepsilon^2} (J_{i+1}^{s+1} - I_i^{s+1}) + G.$$  

(A.1)

The microscopic flux $\zeta$ is computed by solving the following initial value problem at the cell boundary $x = x_{i+\frac{1}{2}}$:

$$\begin{cases} 
\frac{I_{i+1}^{s+1} - I_i^s}{\Delta t} + \frac{1}{\Delta x}(\zeta_{i+\frac{1}{2}} - \zeta_{i-\frac{1}{2}}) = c\sigma_{a,i} \left( \frac{(T_{i+1}^{s+1})^4}{4\pi} - I_{i}^{s+1} \right) + \frac{c\sigma_{s,i}}{\varepsilon^2} (J_{i+1}^{s+1} - I_i^{s+1}) + G, \\
I(t,x)|_{t=t_s} = I(t_s,x,n). 
\end{cases}$$  

(A.1)

In the UGKS scheme, we firstly assume the coefficients $\sigma_a$ and $\sigma_s$ in space and time are piecewise constant, thus the radiative transfer equation in RMHD system (4.1) is equivalent to

$$\frac{d}{dt} e^{\mu t} I(t,x + \frac{cm}{\varepsilon} t,n) = e^{\mu t} \left( \frac{c\sigma_s}{\varepsilon^2} J \left( t, x + \frac{cm}{\varepsilon}, n \right) + \frac{c\sigma_a}{4\pi} T^4 \left( t, x + \frac{cm}{\varepsilon}, t, n \right) + G \right),$$  

(A.2)
with \( \mu = \frac{2 \sigma_a + \sigma_s}{\epsilon} \). Solving the equivalent equation (A.2) with the initial value in the system (A.1), which gives the solution

\[
I(t, x_{i+\frac{1}{2}}, n) \approx e^{-\mu_{i+\frac{1}{2}}(t-t_s)} I \left( t_s, x_{i+\frac{1}{2}} + \frac{c n}{\epsilon} (t - t_s) \right) + \frac{1 - e^{-\mu_{i+\frac{1}{2}}(t-t_s)}}{\mu_{i+\frac{1}{2}}} \hat{G}_{i+\frac{1}{2}}
+ \int_{t_s}^{t} e^{-\mu_{i+\frac{1}{2}}(t-t_s)} \left( \frac{c \sigma_a + \frac{1}{2}}{\epsilon^2} J \left( z, x_{i+\frac{1}{2}} - \frac{c n}{\epsilon} (t - z) \right) + \frac{c \sigma_a + \frac{1}{2}}{4\pi} T^4 \left( z, x_{i+\frac{1}{2}} - \frac{c n}{\epsilon} (t - z) \right) \right) dz,
\]

with \( \mu_{i+\frac{1}{2}}, \sigma_{a,i+\frac{1}{2}} \) and \( \sigma_{s,i+\frac{1}{2}} \) being the constant value at the corresponding cell boundary for \( \mu, \sigma_a \) and \( \sigma_s \) respectively. In solution (A.3), there remains three terms that need to approximate: the first one is the initial condition \( I(t_s) \) around \( x_{i+\frac{1}{2}} \), namely the function \( I \left( t_s, x_{i+\frac{1}{2}} + \frac{c n}{\epsilon} (t - t_s) \right) \); the second one is the two functions \( J, T^4 \) localized in the time interval \( [t_s, t_{s+1}] \) and around the boundary \( x_{i+\frac{1}{2}} \), i.e., the functions \( J \left( z, x_{i+\frac{1}{2}} - \frac{c n}{\epsilon} (t - z) \right) \) and \( T^4 \left( z, x_{i+\frac{1}{2}} - \frac{c n}{\epsilon} (t - z) \right) \); the last one is the term \( \hat{G}_{i+\frac{1}{2}} \).

The first term: For the first term, a piecewise linear reconstruction function is used to approximate the initial function \( I(t_s) \) around \( x_{i+\frac{1}{2}} \):

\[
I(t_s, x, n) = \begin{cases} I_s^+ + \delta_x I_s^+(x - x_i), & \text{if } x < x_{i+\frac{1}{2}}, \\ I_{s+1}^- + \delta_x I_{s+1}^-(x - x_{i+1}), & \text{if } x > x_{i+\frac{1}{2}}. \end{cases}
\]

Here \( \delta_x I_s^+ \) is the limited slope determined by the minmod limiter [26]:

\[
\delta_x I_s^+ = \begin{cases} \min \left( \frac{I_{i+1}^- - I_i^+}{\Delta x}, \frac{I_{i+1}^- - I_{i-1}^-}{2\Delta x}, \frac{I_{i+1}^- - I_{i-1}^-}{\Delta x} \right), & \text{if all are positive}, \\ \max \left( \frac{I_{i+1}^- - I_i^+}{\Delta x}, \frac{I_{i+1}^- - I_{i-1}^-}{2\Delta x}, \frac{I_{i+1}^- - I_{i-1}^-}{\Delta x} \right), & \text{if all are negative}, \\ 0, & \text{otherwise}. \end{cases}
\]

The second term: For the second term, the approximations of two functions \( J \) and \( T^4 \) between \( t_s \) and \( t_{s+1} \)
and around \( x_{i+\frac{1}{2}} \) are constructed in the same manner, so only the approximation of \( J \) is introduced in detail.

The function \( J \) is treated implicitly in time by using piecewise linear polynomials, so the reconstruction for \( J \) reads:

\[
J(t, x) = \begin{cases} J_s^{i+\frac{1}{2}} + \delta_x J_s^{i+\frac{1}{2}}(x - x_i), & \text{if } x < x_{i+\frac{1}{2}}, \\ J_{s+1}^{i+\frac{1}{2}} + \delta_x J_{s+1}^{i+\frac{1}{2}}(x - x_{i+1}), & \text{if } x > x_{i+\frac{1}{2}}. \end{cases}
\]

with the interface value of \( J \) defined by

\[
J_s^{i+\frac{1}{2}} = \left( J_s^{i+1}(n) \right) = \frac{1}{2} \left( J_s^i + J_s^{i+1} \right),
\]

and with the spatial derivatives given by

\[
\delta_x J_s^{i+1,+} = \frac{J_s^{i+1} - J_s^i}{\Delta x / 2}, \quad \delta_x J_s^{i+1,-} = \frac{J_s^{i+1} - J_s^i}{\Delta x / 2}.
\]

The third term: At last, the approximation for the term \( \hat{G} \) is discussed. Recall the definition of \( G_i \):

\[
G_i = 3 \varepsilon [\sigma_{a,i} + n_{s,i} v_{s,i}^2 \left( \frac{v_{s,i}^4}{4\pi} - J_s^{i+1} \right) + n v_{x,i}^2 \left( \varepsilon \sigma_{a,i} + \frac{\sigma_{s,i}}{\varepsilon} \right) (4 J_s^{i+1} + \varepsilon (n R_{s}^{i+1} + Q_{s}^{i})) - \frac{2}{3} \sigma_{s,i} v_{x,i}^4 R_{s}^{i+1} - \frac{(\varepsilon^2 \sigma_{a,i} - \sigma_{s,i}) (v_{x,i}^4)}{c} (\frac{2}{3} J_s^{i+1} + \varepsilon K_{s,i}^i),
\]
The upwind scheme is used to determine $\tilde{G}$, i.e., the value of $\tilde{G}$ at the center of the interval $[x_i, x_{i+1}]$ is determined by the velocity field $v$ at the both sides boundary,

$$
\begin{align*}
\tilde{G}_{i+\frac{1}{2}, 1} &= G_i, \quad \text{if} \quad \frac{(G_{i+1} - G_i)}{(v_{x,i+1} - v_{x,i})} > 0, \\
\tilde{G}_{i+\frac{1}{2}, 1} &= G_{i+1}, \quad \text{if} \quad \frac{(G_{i+1} - G_i)}{(v_{x,i+1} - v_{x,i})} \leq 0; \\
\tilde{G}_{i+\frac{1}{2}, 2} &= \tilde{G}_{i+\frac{1}{2}, 1}, \quad \text{if} \quad v_{x,i+1} > 0, \\
\tilde{G}_{i+\frac{1}{2}, 2} &= \tilde{G}_{i+1}, \quad \text{if} \quad v_{x,i+1} < 0, \\
\tilde{G}_{i+\frac{1}{2}, 3} &= 0, \quad \text{if} \quad v_{x,i} \leq 0 \leq v_{x,i+1},
\end{align*}
(A.7)
$$

**Appendix B. The full discretization for the equilibrium regime**

Here, we will show the full discretization for system (2.11). Applying semi-implicit finite volume scheme in system (2.11), the fully discretization of (2.11) is same with (4.3) except the RTE and source terms $S_{re}$ and $S_{rp}$, which read:

$$
\frac{J_{i}^{s+1} - J_{i}^{s}}{\Delta t} + \varepsilon n R_{i}^{s+1} + Q_{i}^{s+1} - n R_{i}^{s} - Q_{i}^{s} + \frac{1}{\Delta x} \left( \tilde{\zeta}_{i+\frac{1}{2}, -} - \tilde{\zeta}_{i-\frac{1}{2}, -} \right) = \frac{c \sigma_{a,i}}{\varepsilon^2} \left( \frac{(T_{i+1}^{s})^4}{4\pi} - J_{i}^{s+1} \right) - \left( \frac{c \sigma_{a,i}}{\varepsilon} + \varepsilon \sigma_{s,i} \right) (n R_{i}^{s+1} + Q_{i}^{s+1}) + \tilde{G}_{i},
$$

with the source term:

$$
\tilde{G}_{i} = 3 \sigma_{a,i} n v_{x,i}^{s+1} \left( \frac{(T_{i}^{s+1})^4}{4\pi} - J_{i}^{s} \right) + n v_{x,i}^{s} \left( \frac{\sigma_{a,i}}{\varepsilon} + \varepsilon \sigma_{s,i} \right) (4 J_{i}^{s+1} + \varepsilon (n R_{i}^{s+1} + Q_{i}^{s}))
$$

and

$$
(S_{re})_{i}^{s+1} = 4 \pi \frac{\sigma_{a,i}}{\varepsilon} \left( \frac{(T_{i}^{s+1})^4}{4\pi} - J_{i}^{s+1} \right) + \frac{4 \pi (\varepsilon \sigma_{s,i} - \varepsilon^3 \sigma_{s,i}) v_{x,i}^{s+1}}{c^2} \left[ \frac{c}{3} R_{i}^{s+1} - v_{x,i}^{s+1} \left( \frac{4}{3} T_{i}^{s+1} + \varepsilon K_{Q,i}^{s} \right) \right],
$$

$$
(S_{rp})_{i}^{s+1} = - \frac{4 \pi (\varepsilon^2 \sigma_{s,i} + \sigma_{a,i})}{c} \left[ \frac{c}{3} R_{i}^{s+1} - v_{x,i}^{s+1} \left( \frac{4}{3} T_{i}^{s+1} + \varepsilon K_{Q,i}^{s} \right) \right] + \frac{4 \pi \sigma_{a,i} v_{x,i}^{s+1}}{c} \left( \frac{(T_{i}^{s+1})^4}{4\pi} - J_{i}^{s+1} \right).
$$

Moreover, the numerical flux $\tilde{\zeta}_{i+\frac{1}{2}, -}$ is defined by

$$
\tilde{\zeta}_{i+\frac{1}{2}, -} = A_{i+\frac{1}{2}, -} n \left( I_{x,i+\frac{1}{2}}^{s+1} \mathbb{1}_{n>0} + I_{x,i+\frac{1}{2}}^{s-1} \mathbb{1}_{n<0} \right) + C_{i+\frac{1}{2}, n} J_{x,i+\frac{1}{2}}^{s+1} + \frac{C_{i+\frac{1}{2}, 2}}{4\pi} n (T_{x,i+\frac{1}{2}}^{s+1})^4 + F_{i+\frac{1}{2}, n} \tilde{G}_{i+\frac{1}{2}, -} + D_{i+\frac{1}{2}, n}^1 n^2 \left( \delta_{s} J_{x,i+\frac{1}{2}}^{s+1} \mathbb{1}_{n>0} + \delta_{s} J_{x,i+\frac{1}{2}}^{s-1} \mathbb{1}_{n<0} \right) + \frac{D_{i+\frac{1}{2}, n}^2}{4\pi} n^2 \left( \delta_{s} (T_{x,i+\frac{1}{2}}^{s+1})^4 \mathbb{1}_{n>0} + \delta_{s} (T_{x,i+\frac{1}{2}}^{s-1})^4 \mathbb{1}_{n<0} \right),
(B.1)
$$
where the coefficients in the numerical flux are given by:

\[
A = \frac{c}{\Delta t \varepsilon \mu} (1 - e^{-\mu \Delta t}),
\]

\[
C^1 = \frac{c^2 \sigma_x}{\Delta t \varepsilon \mu} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right), \quad C^2 = \frac{c^2 \sigma_a}{\Delta t \varepsilon^2 \mu^2} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right),
\]

\[
D^1 = -\frac{c^2 \sigma_x}{\Delta t \varepsilon^2 \mu^2} \left( \Delta t (1 + e^{-\mu \Delta t}) - \frac{2}{\mu} (1 - e^{-\mu \Delta t}) \right),
\]

\[
D^2 = -\frac{c^2 \sigma_a}{\Delta t \varepsilon^4 \mu^2} \left( \Delta t (1 + e^{-\mu \Delta t}) - \frac{2}{\mu} (1 - e^{-\mu \Delta t}) \right),
\]

\[
F = \frac{c}{\Delta t \varepsilon \mu} \left( \Delta t - \frac{1}{\mu} (1 - e^{-\mu \Delta t}) \right),
\]

with \( \mu = \frac{\sigma_a + \varepsilon^2 c \sigma_x}{c} \), and \( \tilde{G}_{i+\frac{1}{2}} \) is defined in the same way with \( \tilde{G}_{i+\frac{1}{2}} \). Moreover, the zeroth and first moments of (B.1) are:

\[
4\pi \frac{J_{i+1} - J_i}{\Delta t} + 2\pi \int_{-1}^{1} \tilde{\zeta}_{i+\frac{1}{2}} - \tilde{\zeta}_{i-\frac{1}{2}} d\xi = \frac{c}{\varepsilon} (S_{re})_{i+1},
\]

(B.3)

where

\[
\int_{-1}^{1} \tilde{\zeta}_{i+\frac{1}{2}} d\xi = \int_{-1}^{1} A_{i+\frac{1}{2}} n \left( I_{i+\frac{1}{2}}^+ I_{n>0} + I_{i+\frac{1}{2}}^- I_{n<0} \right) d\xi + \frac{2D_{i+\frac{1}{2}}^1 J_{i+1}^{s+1} - J_i^{s+1}}{3 \Delta x} + \frac{D_{i+\frac{1}{2}}^2 (T_{i+1}^{s+1})^4 - (T_i^{s+1})^4}{6\pi \Delta x} \left[ \frac{\sigma_a}{\varepsilon} v_{i+\frac{1}{2}} + \frac{\sigma_s}{\varepsilon} (\frac{8}{3} J_{i+\frac{1}{2}}^{s+1} + 2\varepsilon K_{Q_i+i+\frac{1}{2}}^s) \right],
\]

(B.4)

where

\[
\int_{-1}^{1} n_{i+\frac{1}{2}} d\xi = \int_{-1}^{1} A_{i+\frac{1}{2}} n^2 \left( I_{i+\frac{1}{2}}^+ I_{n>0} + I_{i+\frac{1}{2}}^- I_{n<0} \right) d\xi + \frac{C_{i+\frac{1}{2}}^1 (J_{i+1}^{s+1} + J_i^{s+1}) + C_{i+\frac{1}{2}}^2 ((T_{i+1}^{s+1})^4 + (T_i^{s+1})^4)}{12\pi} \left( \frac{2}{5} R_{i+\frac{1}{2}}^{s+1} + \int_{-1}^{1} n^3 Q_{i+\frac{1}{2}}^s d\xi \right) - \frac{4}{9} \varepsilon^2 \sigma_{s,i+\frac{1}{2}} v_{i+\frac{1}{2}} R_{i+\frac{1}{2}}^{s+1}
\]

and

\[
- \frac{2(\sigma_{a,i+\frac{1}{2}} - \sigma_{s,i+\frac{1}{2}}) v_{i+\frac{1}{2}}^{s+1}}{3c} \left( \frac{4}{3} J_{i+\frac{1}{2}}^{s+1} + \varepsilon K_{Q_i+i+\frac{1}{2}}^s \right).
\]

At last, we will give the diffusion limit of the full discretization of the equilibrium case. Firstly, assuming \( \sigma_a \) and \( \sigma_s \) are positive, as \( \varepsilon \to 0 \), the leading order of the coefficients in the numerical flux (B.1) are

\[
A(\Delta t, \varepsilon, c, \sigma_a, \sigma_s) = 0 + O(\varepsilon),
\]

\[
\varepsilon C^1(\Delta t, \varepsilon, c, \sigma_a, \sigma_s) = 0 + O(\varepsilon), \quad \varepsilon C^2 = c + O(\varepsilon),
\]

\[
D^1 = 0 + O(\varepsilon), \quad D^2 = -\frac{c}{\sigma_a} + O(\varepsilon),
\]

\[
\frac{1}{\varepsilon} F = \frac{1}{\sigma_a} + O(\varepsilon).
\]

which means the zeroth moment and the first moment of the numerical flux, as \( \varepsilon \to 0 \), have the following limit:

\[
\int_{-1}^{1} \tilde{\zeta}_{i+\frac{1}{2}} d\xi \to \frac{8}{3} v_{i+\frac{1}{2}}^{s+1} J_{i+\frac{1}{2}}^{s+1} - \frac{2c}{3\sigma_{a,i+\frac{1}{2}}} J_{i+1}^{s+1} - J_i^{s+1} \Delta x,
\]

(B.5)
\[ \frac{\varepsilon}{4\pi} \sigma_{a,1} \left( \frac{(T_{i+1}^{s+1})^4}{4\pi} - J_{i+1}^{s+1} \right) = 0. \]  

In equation (B.3), letting \( \varepsilon \to 0 \), one can obtain

Multiplying equation (B.3) by \( P_0 \), adding it to energy equation and substituting limit (B.5) into the equation, then multiplying equation (B.4) by \( \varepsilon P_0 \), adding it to momentum equation and substituting limit (B.6) into the equation, at last letting \( \varepsilon \to 0 \) in the two equations, one can obtain

\[
\begin{align*}
\frac{\alpha}{\Delta t} (\rho T)^{s+1} + (\rho v^2 + B^2)^{s+1} - (\rho v^2 + B^2)^{s} + \frac{P_0}{\Delta t} (T_{i+1}^{s+1})^4 - (T_{i}^{s+1})^4 + \frac{1}{\Delta x} (F_{3,i+\frac{1}{2}}^{s} - F_{3,i-\frac{1}{2}}^{s}) \\
+ 4 P_0 \frac{\sigma_{a,i+\frac{1}{2}}^{s+1}}{3} (T_{i+\frac{1}{2}}^{s+1})^4 - \sigma_{a,i-\frac{1}{2}}^{s+1} (T_{i-\frac{1}{2}}^{s+1})^4 = \frac{P_0 c}{3\sigma_{a,i+\frac{1}{2}} \Delta x} (T_{i+1}^{s+1})^4 - (T_{i}^{s+1})^4 - \frac{P_0 c}{3\sigma_{a,i-\frac{1}{2}} \Delta x} (T_{i+1}^{s+1})^4 - (T_{i-1}^{s+1})^4,
\end{align*}
\]

which are fully discretization for (2.14c) and (2.14b).
